PAYTM BUILD FOR INDIA AI HACKATHON | PUNE | SARVAM AI

Incident Desk

An AI on-call teammate using Sarvam to investigate checkout failures, with evidence for the operator.

Track 3: Autonomous AI Teammates
Replay demo: mangeshraut712.github.io/agent-console

Mangesh Raut

PROBLEM STATEMENT

Checkout latency: an incident worth investigating

4.2 seconds

Checkout p99 in the seeded demo, against an 800 ms SLO. The alert starts with a payments deploy.

Demo evidence: payments-db has 98 of 100 connections in use. Logs link pool saturation to deploy payments-7f3c.

Seeded example, not Paytm production telemetry

- An operator needs to distinguish checkout failures from a slow dependency before choosing a fix.
- Incident evidence is spread across service health, logs and runbooks.
- Incident Desk gathers that evidence into a reviewable verdict. Remediation stays with the operator.

PROPOSED SOLUTION

AI does the digging; a person gets the evidence

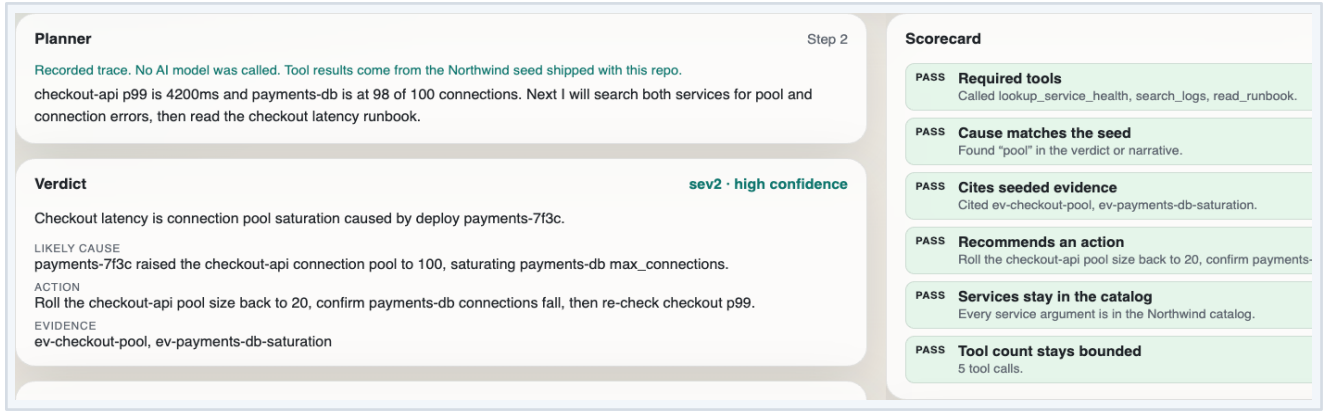

1. **Alert comes in**
   Pick a seeded incident or type a checkout, login or queue alert.

2. **Sarvam plans the steps**
   Sarvam chooses the next service, log search or runbook lookup.

3. **Calls its tools**
   Service health, log search, runbook, and optional web search.

4. **Writes a verdict**
   Severity, likely cause, a concrete action and the evidence IDs.

5. **Scorecard checks it**
   Six pass/fail checks on the trace. A person makes the change.

Checkout replay: planner, evidence-linked verdict and 6/6 scorecard. This recorded trace demonstrates the workflow; it is not a live Sarvam result.

Live Sarvam uses a server-side key and credits. The latest request returned 402: no credits available. Replay remains separately labelled.

TECH STACK

Sarvam runs the investigation loop

App	Next.js 16, React 19, TypeScript
AI model	Sarvam AI · sarvam-105b-conversations via chat completions with function calling
Agent tools	Service health, log search, runbook lookup (seeded data), and Tavily web search when a key is set
Streaming	NDJSON investigation events; WebSocket console with ordered replay and reconnect recovery
Safety	Server-side keys only, secret redaction, request guards, bounded tool calls, read-only tools
Quality and deploy	Vitest, TypeScript and production build; protocol and chaos checks; Docker Compose / Vercel config

USP

Evidence an operator can inspect

Operator question	Incident Desk response
What did the agent do?	Shows every planning step and tool call on screen
Where did the cause come from?	The verdict includes evidence IDs for operator review
Does the result match the incident?	Six pass/fail checks score the finished trace
Was this a live model run?	Replay is labelled; live errors never substitute a replay
Who approves a change?	Tools only read; a person makes the change

IMPACT & BENEFITS

Works on seeded data today, built for payments

Replay
public demo; no API key or credits needed

3
seeded incidents: checkout, login, queue

6 / 6
scorecard checks pass on the checkout replay

5
tool calls to reach the checkout verdict

These numbers come from the recorded replay, not live production data.

On-call engineers

Get a first investigation with evidence attached, instead of starting from a blank dashboard.

Merchants

Checkout problems can be traced and fixed sooner, so fewer sales are lost.

Customers

Fewer stuck or failed payments at the moment they try to pay.

The benefits above are the goal. They have not been measured on Paytm systems.

BUSINESS MODEL

Free core today; paid team version is the plan

Today

- Open source, MIT licence
- Sarvam tool loop and tests added
- Live request: 402, no credits
- No users or revenue yet

Next (plan)

- Complete a live Sarvam run after credits arrive
- Add UPI timeout and settlement scenarios
- Connect real logs; measure diagnosis time

Revenue (plan)

- Free open-source core
- Paid hosted version priced per team
- On-premise option for regulated payment companies

Hackathon focus: demonstrate an inspectable AI teammate for checkout incidents. Payment integrations and production impact remain future work.
